

White Paper: Virtual Leased Line

Executive Summary: Virtual Leased Line (VLL) for high throughput and high reliability Enterprise Branch Office Communications

The Truffle™ Broadband Bonding Network Appliance enables enterprise branch offices to have reliable high performance data connectivity to their main headquarter office datacenters and to the public Internet. Each branch office is enabled with this fast Internet pipe by bonding multiple cost-effective transport technologies such as DSL via Truffle. The Internet lines to be bonded may be from different carriers for ISP diversity to

increase reliability. Additionally, leveraging the high bandwidth connectivity present at the main office of the enterprise, Truffle provides the branch office facility with reliable, high performance Internet access at a fraction of the cost of single provider solutions. In this brief white-paper, we explain how Truffle can save enterprises with branch offices on their monthly Internet access cost, with a return on investment as low as a few months.

Challenge: Data connections between an enterprise headquarters facility and branch offices are unreliable, not fast enough and expensive.

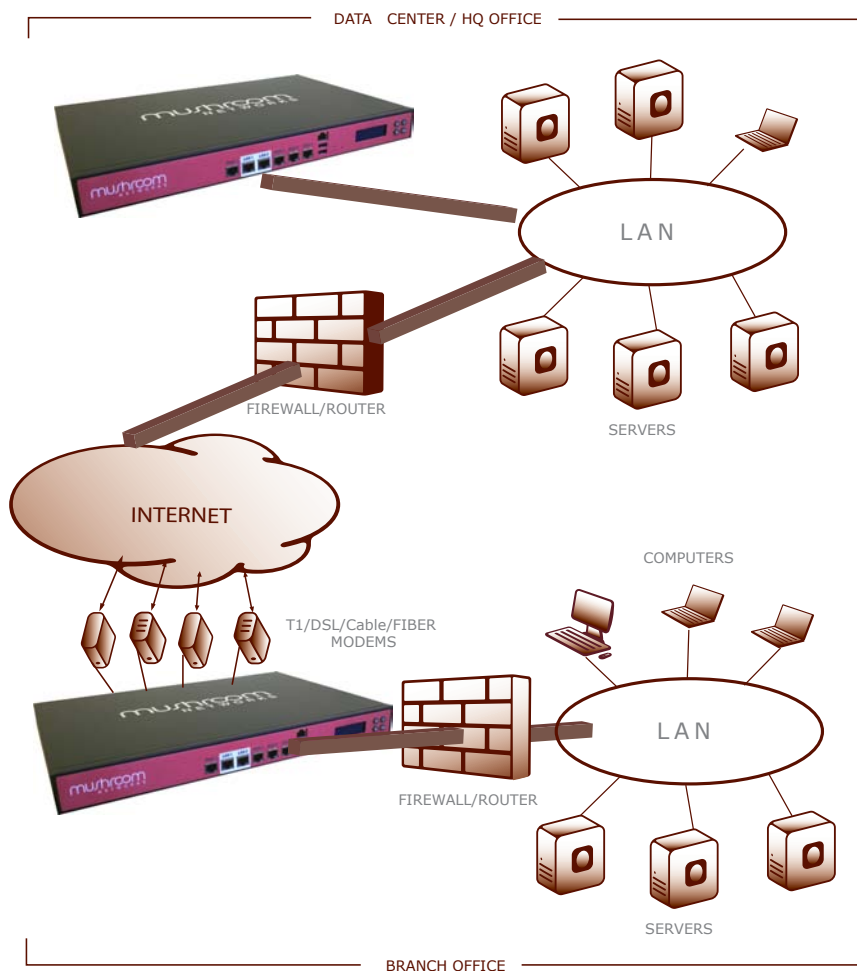

Enterprises that have a headquarter facility such as a main office or data-center and various branch offices need to communicate between all offices as well as with devices and servers on the public Internet. With the proliferation of cloud services based on private and public clouds, as well as services that are heavily dependent on reliable and high-performance applications have saturated the limits of available WAN (Wide Area Network) services. Although it may be economically feasible to provide high bandwidth Internet connectivity to the main office, providing the same speed connections to each branch office is prohibitively expensive since there may be many branch offices and the available Internet services might be limited or costly. Due to security considerations, typically all data communications between offices are transmitted via VPN, sometimes including Internet access, and funneled through the main office facility. Thus, for the data connection between the main office datacenters and the branch office, having a high throughput IP tunnel that is very reliable is critical

If the branch office uses a single DSL, T1 or cable modem connection to communicate to the headquarter office, this will provide insufficient throughput and speed, particularly for uploading data from the branch office to the main office. Similarly, a single broadband line at the branch office, will not provide the adequate up-time that the business critical applications demand.

White Paper: Virtual Leased Line

Solution: Leveraging low cost transport technologies and carrier diversity for fast and reliable connectivity between branch offices and datacenter.

Virtual Leased Line (VLL) enables bonding of multiple Internet access resources such as DSL, Cable or any other IP transport, to provide reliable high throughput data channels. Truffle™ can be installed at the main-office/data-center (master unit) and at a branch office as illustrated below. This architecture will enable a high-speed IP communication framework between the branch office and the headquarters, as well as between the branch offices.

White Paper: Virtual Leased Line

The two Truffle devices form a transparent high-speed data tunnel between them by combining access resources on each side. To illustrate, suppose the enterprise data-center has a DS3 (or fiber) connection that provides the data-center with a symmetric 45Mbps pipe to the Internet. At the branch office, suppose four ADSL lines are plugged into the WAN ports of the Truffle device installed there. Suppose each of the ADSL lines provides a 6Mbps pipe in the downlink direction and a 768kbps pipe in the uplink direction.

Benefits: High speed connectivity from branches to the headquarters/datacenter.

In this example, the four ADSL lines provide an aggregate capacity of 3Mbps (4 x 768Kbps) in the uplink direction and 24Mbps (4 x 6Mbps) in the downlink direction. These lines are in fact aggregated by the Truffle device, and provide a 3Mbps pipe from the branch office to the main office and a 24Mbps pipe from the main office to the branch office.

Benefits: High Speed general Internet access at the branch office.

If desired, the branch office can use the 24Mbps/3Mbps pipe that connects it to the main office for general Internet access. On the other hand, the Truffle device at the branch office can leverage the 24Mbps aggregate download capacity for HTTP downloads directly rather than being routed through the main office. Thus, the users at the branch office facility can enjoy an Internet access with downloads up to 24Mbps and upload speeds of up to 3Mbps.

Benefits: High 9's reliable WAN connectivity for all branch offices.

The overlay bonding tunnel, VLL, is similar conceptually to a VPN tunnel in the sense that there is a logical connectivity path between the two Truffle points. This provides, Application Armor™, the ability for the VLL tunnel to shield any ISP outages from the applications that are utilizing the bonded VLL tunnel. For the branch office to lose their application session, all of the ISPs that are bonded need to have disconnect events at the same time, which is a very low probability event compared to a single Internet connection disconnecting. VLL can bond various types of Internet connections from any service provider including DSL, Cable, MPLS, T1, E1 or any other IP based Internet connectivity.

Benefits: 75% cost reduction on monthly Internet access fees & quick ROI (Return on Investment).

Compared to using a T1 line or a bonded T1 line, VLL solution provided by Truffle units will save up to 75% on the bandwidth expenditure per month. For example, a typical price for bonded T1 service is \$800 per month. Rather than using bonded T1, which has a throughput of 3Mbps in each direction, the business can use four 6Mbps/768kbps DSL lines with the Truffle bonding solution. This provides the branch office with a faster 24Mbps/3Mbps data connection at a fraction of the cost. A typical price for business DSL is \$50 per month, so the cost of four DSL lines is approximately \$200 per month. This results in a savings of \$600 per month, a 75% savings on monthly fees and therefore paying for the Truffle equipment in less than a few months.

White Paper: Virtual Leased Line

Similarly, consider the case where a T1 line is used, which typically costs around \$400 per month. Instead, this could be replaced by 2 DSL lines resulting in a savings of approximately \$300 per month.

These calculations do not factor in the added value of high speed general Internet access at the branch office that is enabled by Mushroom Networks' VLL solution. In the example above, a 24Mbps down / 3 Mbps up Internet access service is provided at a cost of \$200 per month. Nor do these calculations take into account that the VLL solution can provide highly reliable service, by combining different types of services from different carriers and providing session continuity for applications even during ISP failures.

Features: Plug and play transparent installation & Advanced Router and Advanced QoS Features.

In situations where the branch office has an existing local network with a single WAN connection, Truffle can be installed without any modification to the existing network, including assignment of IP addresses and the existing firewall configuration. This makes the installation of the VLL solution very easy and quick with minimal down time of an operational network.

Truffle has advanced router features, which can be optionally enabled at no additional cost. A notable feature is the Adaptive Quality of Service features enabling dynamic bandwidth reservation for selected applications and traffic types, that adaptively reserves bandwidth only when that traffic type is detected. One can also limit inbound/outbound traffic to defined bit rates, bind certain traffic types on to specified WAN links, manipulate traffic based on TOS identifier, block certain traffic types. An example use case for this is for VOIP traffic, whereby the VOIP traffic is protected from congestion from other inbound/outbound traffic. Many company network administrators currently provision dedicated access lines that only carry VoIP traffic, to prevent QoS degradation. The VOIP module present on the Truffle enables user defined rate limiting of non-real-time traffic so that real-time traffic, such as VOIP traffic, does not suffer unacceptable QoS degradation due to non-real-time traffic, for example file downloads.

The Truffle includes a full function stateful firewall, which can optionally be enabled. Flows can be defined by source IP address, destination IP address, source port, and destination port, and protocol number, and each such flow can be selectively blocked (outgoing) or selectively unblocked (incoming).

Truffle can be easily configured so that traffic to certain external public IP addresses and ports numbers can be forwarded to local servers and hosts with internal private IP addresses and ports, a feature called port forwarding. A DMZ feature is included so that all incoming traffic not matching certain criteria are sent to a "DMZ" server, to facilitate advanced security.

White Paper: Virtual Leased Line

Truffle also supports a feature called Interface binding, which allows an operator control to pin down certain types of traffic to a particular interface during normal conditions. This allows the operator maximum flexibility for configuring the Truffle for operation in many application environments.

Truffle can be configured to automatically send out email alarm messages after critical events. Truffle is easily managed through an easy to use web-based graphical user interface, which can either be accessed locally, or remotely, via a password. SNMP support is included (MIB 2, read-only).

Traffic Monitoring module provides applications specific layer7 identifiers of traffic provides pin-point control of your traffic within the network. A graph based traffic monitoring is also available with histograms over seconds, minutes, hours, days, months and years. Scalable design of the Truffle, enables IT personnel to easily and quickly deploy Truffles in large scale. The remote manageability, remote firmware upgrades, configuration backups, CLI scripting options, hot-fail over dual install options enables enterprises with the highest level of uptime with ease.

Conclusion:

Truffle provides a unique fast, high 9s reliable and inexpensive data connectivity between the main-office / data-center of an enterprise with its branch offices, by bonding low cost transport technologies, such as DSL, cable or any other IP based Internet connection. Compared to the alternative of using a single and expensive Internet line, VLL solution reduces WAN expenses for an enterprise around 75% per month. As an added benefit, reliable general Internet access can be provided for the branch office through the Internet connection at the main office.

About Mushroom Networks, Inc

Mushroom Networks is a San Diego, California-based company with the mission to provide innovative networking solutions. Our products and services are focused on a range of networking solutions for enterprises and small/medium sized businesses in various industries. Our solutions bridge the technology gap to the future by enabling applications today, that are otherwise not possible. Mushroom Networks was founded in 2004 as a spin-off from the University of California at San Diego. Mushroom Networks' products are based on the unique and patented Broadband Bonding® technology developed by our engineering team through extensive research & development.

Mushroom Networks Product & Technology Awards:
