

Metal Industry Indicators

Indicators of Domestic Primary Metals, Steel, Aluminum, and Copper Activity

February 2018

The primary metals leading index and its 6-month smoothed growth rate both increased in January. In addition, the primary metals leading index 6-month smoothed growth rate has been above the +1.0% threshold since April 2016, which could suggest near term strength in primary metals industry activity (table 2). From April 2016 through April 2017, the U.S. nonferrous metal products inventories growth rate recorded a run of consecutive negative growth rates, May, June and July 2017 were a pause in the trend, negative growth rates resumed August through December (table 1); Inventory decreases indicate increased consumption in nonferrous metal products. In January 2018, the primary aluminum and primary copper 6-month smoothed growth rates posted their seventeenth and fifteenth consecutive months with positive double digit growth rates, respectively (table 1). The steel scrap 6-month smoothed growth rate had double digit positive growth rates November 2016 through September 2017, paused in October and November 2017, and resumed in December 2017 and January 2018 (table 1).

The **primary metals leading index** increased to 173.8 in January from a downwardly revised 168.4 in December, and its 6-month smoothed growth rate increased to 9.3% in January from a downwardly revised 3.7% in December (table 2). The 6-month smoothed growth rate is a compound annual rate, which measures near-term trend. Usually, a growth rate above +1.0% signals an increase in metals activity, and a growth rate below -1.0% indicates a downturn in activity. The primary metals leading index growth rate had posted growth rates above +1.0% from April 2016 through January 2018, which could signal strength in primary metals industry activity. Of the four indicators that were available to calculate the January leading index, primary metals average weekly hours [1.3] and machinery, construction and farm and industrial S&P stock price index [0.7] provided the two largest positive contributions (table 3). There were no negative contributions to the primary metals leading index for January. The January leading index should be considered preliminary because only four of its eight indicators were available, and the leading index will

be subject to revision when the other components are added next month.

The **steel leading index** increased to 115.2 in December from an upwardly revised 114.1 in November, and its 6-month smoothed growth rate increased to 0.2% in December from an upwardly revised -1.6% in November (table 4). Since April 2017 the steel leading index growth rates have been below the +1.0% growth rate threshold, and in November fell below the -1.0% growth rate threshold, which could indicate near-term weakness in steel industry activity, however, December's growth rate was marginally positive again. The largest positive contribution to the steel leading index in December was the S&P stock price index of steel companies [0.4] (table 5). The largest negative contribution was iron and steel mills new orders [-0.1] (table 5).

The **copper leading index** decreased to 128.0 in December from a downwardly revised 129.5 in November, and its 6-month smoothed growth rate

decreased to -0.4% in December from a downwardly revised 2.0% in November (table 6). Since June 2017 the copper leading index growth rate had been above the +1.0% threshold, but the growth rate turned marginally negative in December (table 6). The two largest positive contributions to the copper leading index in December were new orders of nonferrous metals products [0.3] and the LME spot price of primary copper [0.3] (table 7). By far the largest negative contribution was nonferrous metals average weekly hours [-1.8] (table 7).

The **leading index of metal prices** increased to 108.3 in December from an upwardly revised 108.0 in November, and its 6-month smoothed growth rate increased to 0.9% in December from an upwardly revised 0.6% in November (table 1). The leading index of metal prices growth rates had been above the +1.0% growth rate threshold since July 2017 until the growth rate dipped below the +1.0% threshold November and December (table 1).

Sources: U.S. Geological Survey (USGS), American Metal Market (AMM), the London Metal Exchange (LME), U.S. Census Bureau, the Organisation for Economic Cooperation and Development (OECD), and Federal Reserve Board.

Note: The components of the Leading Index of Metal Prices are the spread between the U.S. 10-year Treasury Note and the federal funds rate, and the 6-month smoothed growth rates of the deflated value of new orders for nonferrous metal products, the Organisation for Economic Cooperation and Development (OECD) Total Leading Index, and the reciprocal of the trade-weighted average exchange value of the U.S. dollar against other major currencies. The Metal Industry Indicators (MII) Nonferrous Metals Price Index measures changes in end-of-the-month prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange (LME). The steel scrap price used is the price of No. 1 heavy melting. Inventories consist of the deflated value of finished goods, work in progress, and raw materials for U.S.-produced nonferrous metal products (NAICS 3313, 3314, & 335929). Six-month smoothed growth rates are based on the ratio of the current month's index or price to its average over the preceding 12 months, expressed at a compound annual rate.

CHART 6.
COPPER: LEADING AND COINCIDENT INDEXES, 1994-2017

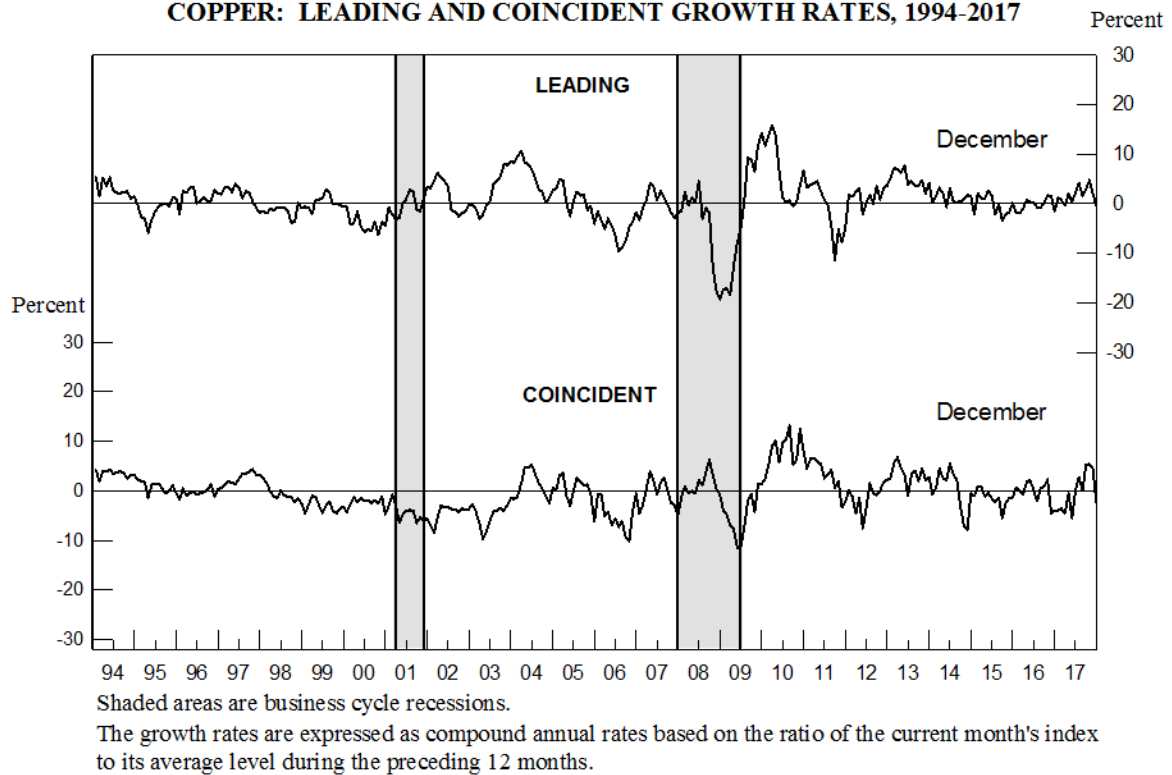

CHART 7.
COPPER: LEADING AND COINCIDENT GROWTH RATES, 1994-2017

Explanation

Each month, the U.S. Geological Survey tracks the effects of the business cycle on three U.S. metal industries by calculating and publishing composite indexes of leading and coincident indicators. Wesley Mitchell and Arthur Burns originated the cyclical-indicators approach for the economy as a whole at the National Bureau of Economic Research in the mid-1930s. Over subsequent decades this approach was developed and refined, mostly at the National Bureau, under the leadership of Geoffrey H. Moore.¹

A business cycle can briefly be described as growth in the level of economic activity followed by a decline succeeded by further growth. These alternating periods of growth and decline do not occur at regular intervals. Composite indexes, however, can help determine when highs and lows in the cycle might occur. A composite index combines cyclical indicators of diverse economic activity into one index, giving decision makers and economists a single measure of how changes in the business cycle are affecting economic activity.

The indicators in the metal industry leading indexes historically give signals several months in advance of major changes in a coincident index, a measure of current metal industry activity. Indicators that make up the leading indexes are, for the most part, measures of anticipations or new commitments to various economic activities that can affect the metal industries in the months ahead.

Composite coincident indexes for the metal industries consist of indicators for production, shipments, and total employee hours worked. As such, the coincident indexes can be regarded as measures of the economic health of the metal industries.

The metal industry coincident indexes reflect industry activity classified by the U.S. Standard Industrial Classification (SIC) and the North American Industry Classification System (NAICS). Of the three metal industries, primary metals (NAICS 331) is the broadest, containing 25 different metal processing industries. Steel and copper are specific industries within the primary metals group.

The SIC was the main vehicle used by the U.S. Government and others in reporting industry economic statistics throughout most of the last century. Starting with the 1997 U.S. Economic Census, the U.S. Government began using the NAICS, which classifies economic data for industries in Canada, Mexico, and the United States. From 1997 onward, the metal industry indexes reflect the NAICS classification, while indexes for earlier years follow the SIC.

The largest change to primary metals because of the NAICS deals with other communication and energy wire manufacturing (NAICS 335929). Under NAICS, this manufacturing was removed from primary metals (NAICS 331) and added to electrical equipment, appliance, and component manufacturing (NAICS 3359). In order to maintain consistency with years before 1997, the USGS estimated values for NAICS 335929 and added them to the appropriate metal industry indicators and indexes for the years after 1997.

In May 2016, the Census Bureau benchmarked the 2008-2011 Annual Survey of Manufactures (ASM) to the revised 2012 Economic Census. While the NAICS has been revised since 1997

¹ Business Cycle Indicators, A monthly report from The Conference Board (March 1996).

and was revised for 2012, the ASM follows the 2007 NAICS. For aluminum and nonferrous metals, the result of this benchmark indicates a slightly lower level of inventories, but no significant contributions for other communication and energy wire.

Because there is no significant contribution to the monthly changes and trend by including estimates of inventories for other communication and energy wire, the USGS will discontinue estimation and including such inventories starting with the June 2016 issue of the Metal Industry Indicators.

The metal industry leading indexes turn before their respective coincident indexes an average of 8 months for primary metals and 7 months for steel and copper.

The leading index of metal prices, also published in the Metal Industry Indicators, is designed to signal changes in a composite index of prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange. On average, this leading index indicates significant changes in price growth about 8 months in advance.

The growth rate used in the Metal Industry Indicators is a 6-month smoothed growth rate at a compound annual rate, calculated from a moving average. Moving averages smooth fluctuations in data over time so that trends can be observed. The 6-month smoothed growth rate is based upon the ratio of the latest monthly value to the preceding 12-month moving average:

$$\left(\left(\frac{\text{current value}}{\text{preceding 12-month moving average}} \right)^{\frac{12}{6.5}} - 1 \right) * 100$$

Because the interval between midpoints of the current month and the preceding 12 months is 6.5 months, the ratio is raised to the 12/6.5 power to derive a compound annual rate.

The growth rates measure the near-term industry trends. They, along with other information about the metal industries and the world economy, are the main tools used to determine the outlook of the industries. A 6-month smoothed growth rate above +1.0% usually means increasing growth; a rate below -1.0% usually means declining growth.

The next update for these indexes is scheduled for release on the World Wide Web at 10:00 a.m. EDT, Friday, March 23. The address for Metal Industry Indicators on the World Wide Web is: <http://minerals.usgs.gov/minerals/pubs/mii/>

The Metal Industry Indicators is produced at the U.S. Geological Survey by the National Minerals Information Center. The report is prepared by Jeffrey Busse (703-648-4914; e-mail: jbusse@usgs.gov). Data provided by Jacob Fuhr and Annie Hwang. The former Center for International Business Cycle Research, under the direction of Dr. Geoffrey H. Moore, and the former U.S. Bureau of Mines developed the metal industry leading and coincident indexes in the early 1990s. Customers can send mail concerning the Metal Industry Indicators to the following address:
