

2009 Minerals Yearbook

POTASH

POTASH

By Stephen M. Jasinski

Domestic survey data and tables were prepared by Linda M. White, statistical assistant, and the world production table was prepared by Lisa D. Miller, international data coordinator.

In 2009, the world potash market collapsed owing to the global economic downturn and a drop in demand. High potash prices in the first half of 2009 contributed to the drop in consumption as farmers delayed purchases until prices fell. This led to high inventories and the temporary closure of many potash mines. World production was less than 50% of rated capacity in 2009; its lowest level since 1993. In the United States, about 1.7 million metric tons (Mt) of minerals was mined to produce 720,000 metric tons (t) of potassium oxide (K_2O) equivalent. U.S. production was at its lowest point since 1943. U.S. potash production was 35% less in 2009 than in 2008, and the total value of sales decreased by 32% from that of 2008. The unit value for potash increased from \$300 per metric ton in 2008 to \$335 per ton in 2009, although this was because of high prices in the first half of the year, which had decreased substantially by yearend. Apparent consumption of potash decreased by 62% from that of 2008, to reach its lowest point since 1962. Imports of potash decreased 62% from those of 2008, while exports increased by 36% (table 1).

Potash denotes a variety of mined and manufactured salts, all of which contain the element potassium in water-soluble form. The majority of domestic potash was produced near Carlsbad, NM, with most of the potash coming from the mineral sylvite. The term potash refers to potassic fertilizers, which are potassium chloride (KCl or sylvite), potassium sulfate [K_2SO_4 or sulfate of potash (SOP), usually a manufactured product], and potassium-magnesium sulfate [$K_2SO_4 \cdot 2MgSO_4$ or langbeinite or double sulfate of potash magnesia (SOPM or K-Mag)]. Muriate of potash (MOP) is an agriculturally acceptable mix of KCl (95% pure or greater) and sodium chloride (halite) for fertilizer use that includes minor amounts of other nontoxic minerals from the mined ore and is neither the crude ore sylvinitite nor pure sylvite.

This publication has historically included potassium nitrate [KNO_3 or saltpeter or nitrate of potash (NOP), a mostly manufactured product] and mixed sodium nitrate and potassium nitrate ($NaNO_3$ and KNO_3 or Chilean saltpeter, a natural product) because these materials function as potassic plus nitrogenous fertilizers. Saltpeter and Chilean saltpeter are still included in the import tables (tables 5, 6).

Production

Domestic production data were developed by the U.S. Geological Survey (USGS) from a semiannual voluntary canvass of U.S. operations. All of the seven operations canvassed for semiannual production data responded to the surveys.

Three companies produced potash from seven operations in three States. Most domestic production was from southeastern New Mexico, where Intrepid Potash, Inc. operated two mines and The Mosaic Company operated one mine. Mosaic also operated a deep-solution mine in Michigan. The third State with potash production was Utah, where Intrepid produced potash

from a solution mine in Moab and from a solar evaporation facility in Wendover, and Great Salt Lake Minerals Corp. (a subsidiary of Compass Minerals International, Inc.) operated a solar evaporation facility in Ogden.

Potash companies in the United States produced MOP, SOP, and SOPM. Published production data of all types and grades of potash in the United States are adjusted to avoid disclosing the proprietary data of companies that produce SOP and SOPM, which together are known as sulfates.

Intrepid continued with its plans to reopen the underground HB Mine, which is located near the company's existing mines in Carlsbad, NM, as a solution potash mine. The HB Mine was closed in 1996 by the previous owner. The facility would increase annual production by 200,000 metric tons of MOP. Intrepid expects the mine to be fully permitted by mid-2011, and production could start about 1 year after that (Intrepid Potash, Inc., 2010, p. 5).

In 2009, domestic consumption of K_2O equivalent was 62% lower compared with that of 2008, owing to the economic recession, high potash prices in the first half of the year, and the subsequent drop in demand. The principal use of potash is as an agricultural fertilizer (plant nutrient) because it is a source of soluble potassium, which is one of the three primary plant nutrients required for plant growth and maturation; the others are fixed nitrogen and soluble phosphorus. Potash and phosphorus are mined products, and fixed nitrogen is produced from the atmosphere using industrial processes. Modern agricultural practice uses large amounts of these primary nutrients and additional nutrients, such as boron, calcium, chlorine, copper, iron, magnesium, manganese, molybdenum, sulfur, and zinc, to ensure plant health and proper maturation. The three major plant nutrients have no cost-effective substitutes. Low-nutrient-content alternative potash sources, such as animal manure and guano, bone meal, compost, glauconite, and "tankage" from slaughterhouses, are available, but the cost of transportation per metric ton of nutrient beyond relatively short distances can reduce their desirability. In addition to its use as a fertilizer, potassium chloride is important in industrialized economies, where it is used in aluminum recycling, by the chloralkali industry to produce potassium hydroxide, in metal electroplating, oil-well drilling mud, snow and ice melting, steel heat-treating, and water softening.

Potassium hydroxide is used for industrial water treatment and is the precursor of potassium carbonate, several forms of potassium phosphate, many other potassic chemicals, and soap manufacturing. Potassium carbonate is used to produce animal feed supplements, cement, fire extinguishers, food products, photographic chemicals, and textiles. It is also used in brewing beer, pharmaceutical preparations, and as a catalyst for synthetic rubber manufacturing. Generally, these nonfertilizer uses have accounted for about 15% of annual potash consumption in the United States.

Foreign Trade

U.S. exports of potash (gross weight) increased slightly in 2009 from those of 2008, owing to increased sales of MOP. Exports of 705,000 t were reported, of which 49% was MOP, 44% was SOPM, 6% was SOP, and 1% was NOP (table 3). Brazil, Mexico, and Canada in declining order, received 54% of the total exports of potash from the United States (table 4). Total potash exports, reported by K₂O content, increased by 36% in 2009 compared with those of 2008.

Potash imports (gross weight) into the United States for 2009 decreased by 62% to 3.67 Mt compared with 9.56 Mt in 2008 (table 5). The leading source of all potash imports was Canada with 88% of the total (table 6).

World Industry Structure

Estimated 2009 world potash production decreased by 40% to 20.8 Mt, with decreased output from all major producing countries, except for China (table 7). The collapse of global trade in response to reduced world demand and the global economic downturn resulted in high producers' stocks and temporary mine closures. Only 13 countries are notable potash producers, with Belarus, Canada, China, Germany, Israel, Jordan, and Russia accounting for about 90% of global production capacity. World potash production in 2009 was at 48% of rated annual capacity (Heffer and Prud'homme, 2010).

World Review

Argentina.—Companhia Vale de Rio Doce (Vale) of Brazil purchased the Rio Colorado potash project from Rio Tinto Plc in early 2009. Vale planned to develop a 4.3-million-metric-ton-per year (Mt/yr) MOP solution mine in Malargue in Mendoza Province beginning in 2011 for completion by 2017 and a solution mine in Neuquen Province in the longer term (Green Markets, 2009).

Canada.—The effects of the world economic downturn and the global drop in potash demand were the main factors in a 60% decrease in Canadian potash production in 2009 compared with 2008. All three major producers—Agrium, Inc., Mosaic, and Potash Corp. of Saskatchewan (PotashCorp)—drastically reduced output in 2009. Despite the economic conditions, potash expansion and exploration projects by major producers and other companies continued during the year, although completion of most of the projects was delayed.

In Saskatchewan, PotashCorp planned to expand and debottleneck its Allan and Cory plants and replace existing mines and expand processing plants in Rocanville, as well at its operation in Sussex, New Brunswick. The projects would increase the company's annual production capacity to 17.1 Mt MOP sometime in 2015 (Stone, 2010).

Mosaic planned to add 300,000 t of annual capacity at its Colonsay and Esterhazy Mines in Saskatchewan by the end of 2011. Agrium planned to expand its potash production capacity at its Vanscoy Mine by 40% by the end of 2015 (Stone, 2010).

Vale acquired the Rio Tinto Regina potash deposit in Saskatchewan in early 2009. Vale planned to develop a 2.8-Mt/yr MOP solution mine sometime after 2015 (Green Markets, 2009).

Outlook

In late 2008, the effects of the global economic recession, combined with high potash prices and weak demand, led to a collapse in the world potash market. The weak market conditions that followed the collapse of the potash market continued throughout 2009. Producers' stocks remained high, and many buyers waited for prices to fall before reentering the market. Early in 2009, most leading world producers announced indefinite reductions in production, which amounted to about one-half of world production capacity. The leading consuming countries, including Brazil, China, India, and the United States, were all projected to have major decreases in consumption in 2010.

Beginning in 2010, world potash production was expected to rebound to close to that of 2008, as producer stocks decreased gradually as consumption recovered. Potash applications will be needed to replenish soil nutrient levels in most regions after the drop in consumption in 2009. According to the International Fertilizer Industry Association (IFA), world potash production was forecast to increase from 20.8 Mt in 2009 to 31.1 Mt in 2010, and consumption was forecast to increase from 24.9 Mt in 2009 to 30.0 Mt in 2010 (Heffer and Prud'homme, 2010). Potash capacity expansion plans remained on schedule, with the expected completion of projects in Canada, Chile, Jordan, and Uzbekistan in 2011 and in Argentina, Belarus, Brazil, Laos, and Russia by 2015.
