Little Cherry Disease (LCD)

• Symptoms
  ▪ Produce cherries of small size and poor color and flavor

• Results
  ▪ Economic losses
  ▪ Tree and orchard removal

Bing Cherries
Pathogens and vectors associated with LCD

1. Little cherry virus 2 (LChV2) *(pathogen)*
   - Transmitted by
     - apple & grape mealybug *(vectors)*
     - Root grafting

2. Western X phytoplasma (WX) *(pathogen)*
   - Transmitted by
     - various leafhopper species *(vectors)*
     - Root grafting
     - Surprising resurgence discovered in 2014

3. Little cherry virus 1 (LChV1) *(pathogen)*
   - Mode of transmission unknown
   - Present at low level throughout WA State
   - Typically found in combination with LChV2 or WX

Control methods for apple mealybug 2016

- A field experiment was conducted to determine the effects of chemical insecticides, however, due to extreme parasitism, all trees/trt groups had low crawler numbers.

- Observed parasitism jumped from affecting approximately 20% of egg laying females in 2014, 70-80% in 2015, and to almost 100% in 2016.

- Parasitoid wasps were identified as *Anagyrus schoenherri*.
AMB biocontrol via parasitoid wasps

• *Allotropus utilis* Muesbeck
  - Discovered in 1939 in Nova Scotia, was exported to British Columbia (in 1938), where it became well established.
  - Credited for reduction in AMB associated with LCD infected trees.

• *Anagyrus schoenherri* discovered in Washington state in 2015.
Grape mealybug phenology and control

- Newly hatched crawlers (0.5 mm)
- Crawlers (1 mm)
- Crawlers (1.5-2 mm)
- Crawlers (3-4 mm)
- Adults (4-5 mm)
- Eggs

Timeline:
- March (Mar)
- April (Apr)
- May (May)
- June (Jun)
- July (Jul)
- August (Aug)

Phenological stages:
- Petal Fall
- Summer
- Systemic
Control methods for grape mealybug (GMB)

• Systemic control
  - GMB-infested 1-yr.-old potted “Bing” trees.
  - Treatments:
    • Admire Pro and Aza-Direct (soil drench systemic)
    • Ultor (foliar-systemic)
    • Centaur (insect growth regulator)
  - Average number of GMB crawlers, nymphs, adults/plant over time.
Significant findings for mealybug control

• AMB – Delayed dormant treatments targeting emerged females is most effective.

• AMB – *Anagyrus schoenherri* was found in WA state, and can reduce populations.

• GMB – Soil-drench systemic compounds and an IGR reduced the nymph and adult numbers on potted ‘Bing’ trees.
The Hunt for Leafhopper Vectors of Western X in Washington Cherries: Year One

1. Conduct survey of leafhoppers in Western X affected orchards.

2. Conduct survey of host plants for leafhoppers and/or WX in affected orchards.

3. Examine the capability of selected leafhopper species to transmit WX phytoplasma.
• Two most abundant leafhopper vector species were *Colladonus geminatus* and *reductus*.
• Greater incidence in neighboring alfalfa field than in orchard.
• Peak in alfalfa observed late May/early June for *C. geminatus*, early June for *C. reductus*.
• *C. reductus* increasing in orchard early August.
Seasonal incidence of *Colladonus* spp. on sticky cards in Mattawa cherry orchards and neighboring sageland.
Incidence of Western X in *C. geminatus* collected in cherry orchard and extra-orchard habitats, 2016

Leafhopper Project Significant Findings

- *Colladonus geminatus* and *C. reductus*, were the most abundant species on sticky cards in cherry trees and in habitats outside of orchards.

- Data from sticky cards placed in extra-orchard habitats (e.g., sageland, weeds, alfalfa) provided new information on alternative habitat/host plants and on seasonal movement patterns of leafhopper vectors.

- Molecular diagnostic testing results of 218 *C. geminatus* and 168 *C. reductus* DNA samples confirmed that both species can carry WX phytoplasma. Most of the WX-positive orchard samples for these species were collected during early May and late July/early Aug.
